\section*{Abstract}

Description Logics (DLs) are knowledge representation formalisms that provide, for example, the logical underpinning of the W3C OWL standards. Conjunctive queries (CQs), the standard query language in databases, have recently gained significant attention for querying DL knowledge bases. Several different techniques are available for a wide range of DLs. Nevertheless, for OWL 1 DL and OWL 2 DL, decidability of CQ entailment is an open problem. So far, the combination of number restrictions, inverse roles, and functionality (or qualified number restrictions) simultaneously and number restrictions caused unsolvable problems. We tackle this problem and present a decidability result for entailment of unions of CQs in a DL with all three problematic constructors. For queries with only simple roles, our result also shows decidability in the logic that underpins OWL 1 DL and we believe that the presented results will pave the way for further progress towards CQ entailment decision procedures for OWL.

\section*{Introduction}

Since conjunctive queries were introduced in the context of Description Logics (DLs) (Calvanese, De Giacomo, and Lenzerini 1998), the topic has gained significant attention. Existing techniques for conjunctive query entailment fail if the queried knowledge base (KB) contains inverse roles, nominals, and functionality (or number restrictions) simultaneously; in this case even decidability was an open problem. We tackle this problem and present a decidability result for entailment of conjunctive queries (CQs) in the very expressive Description Logic (DL) \textit{ALCHOIQ} (Baader et al. 2003), which contains all three problematic constructors simultaneously.

Given the variety of recent publications which show a great interest in the problem of conjunctive query entailment over expressive DLs, it is very interesting that for the DLs \textit{SHIF}, \textit{SHOIN}, and \textit{SROIQ} that underpin the widely adopted standards OWL Lite, OWL 1 DL, and OWL 2 DL, respectively, decidability of conjunctive query entailment has only been established for OWL Lite. The critical combination of inverse roles (I), nominals (O), and number restrictions/counting quantifiers (F for functionality, N for unqualified number restrictions, and Q for qualified number restrictions) caused also a major hurdle in the development of implementable algorithms for knowledge base satisfiability in \textit{SHOIN} and extensions thereof, but in 2005, Horrocks et al. devised a tableaux-based decision procedure (Horrocks and Sattler 2005) that has since been extended to \textit{SROIQ}. Meanwhile also alternative approaches such as resolution (Kazakov and Motik 2008), and hypertableaux based procedures (Motik, Shearer, and Horrocks 2009) are available and implemented.

The key obstacle in establishing a decision procedure is the existence of potentially infinitely many new nominals, i.e., elements that are uniquely identifiable in any model of a KB. For an example, consider a KB \( \mathcal{K} \) containing the axioms \( \{ o_1 \} \sqsubseteq \exists f.\exists s.\exists f^-.\{ o_2 \}, \{ o_2 \} \sqsubseteq \exists f.\exists s.\exists f^-.\{ o_3 \}, \{ o_3 \} \sqsubseteq \exists f.\exists s.\exists f^-.\{ o_1 \} \) for \( f \) a functional role (see Figure 1). Due to the functionality of \( f \), each nominal \( o_i \) can have only one \( f \) successor, which forces the existence of an \( s \)-cycle. A cyclic Boolean query such as \( \{ s( x, y ), s( y, z ), s( z, x ) \} \) that checks for the existence of such a cycle cannot be answered by replacing variables with individual names \( o_i \) nor can we rewrite the query into an equivalent tree-shaped query. The elements in the cycle behave as if they were nominals, but we do not have names for them.

    (o1) edge (s1)
    (s1) edge (o2)
    (s2) edge (o2);
\end{tikzpicture}
\caption{A representation for a model of \( \mathcal{K} \), where the three elements in the \( s \)-cycle are so-called \textit{new nominals}.}
\end{figure}

We tackle the problem of conjunctive query entailment in a very expressive DL that contains all the three problematic constructors simultaneously and prove decidability of (unions of) conjunctive queries. The most challenging part is to establish finite representability of countermodels in case the query given as input is not entailed by the knowledge base. Our results also hold for \textit{SHOIQ} knowledge bases, i.e., with some roles declared as transitive, provided that the queries contain
only simple roles (roles that are neither transitive nor have a transitive subrole). This is essentially the same restriction that is placed on roles that can occur in number restrictions since otherwise the standard reasoning tasks become undecidable. Under this restriction, we can use standard techniques for eliminating transitivity (Kazakov and Motik 2008). Hence, we also show decidability of conjunctive query entailment in OWL DL, for queries with only simple roles.

We believe that our work is also valuable for understanding, in general, the structure of models in DLs that contain nominals, inverse roles, and number restrictions. Furthermore, we devise non-trivial extensions of standard techniques such as unraveling, which we believe will prove useful when working with such expressive DLs.

Full proofs and additional material can be found in the accompanying technical report (Glimm and Rudolph 2009).

Related Work

Conjunctive queries have been introduced in the context of Description Logics (DLs) by Calvanese, De Giacomo, and Lenzerini 1998. In particular in recent years, the problem of decidability of conjunctive query entailment and the complexity of the problem in different logics has gained significant attention. For the DLs S$\Pi$IQ and S$\Pi$OQ decidability and 2-ExpTime-completeness of the problem is known (Glimm et al. 2008; Glimm, Horrocks, and Sattler 2008; Eiter et al. 2009). Conjunctive query entailment is already 2-ExpTime-hard in the relatively weak DL ALCI (Lutz 2008), which was initially attributed to inverse roles. Recently, it was shown, however, that also transitive roles together with role hierarchies as in the DL S$\Pi$ make conjunctive query entailment 2-ExpTime-hard (Eiter et al. 2009). The techniques by Glimm et al. for S$\Pi$IQ and S$\Pi$OQ (Glimm et al. 2008; Glimm, Horrocks, and Sattler 2008) reduce query entailment to the standard reasoning task of knowledge base satisfiability checking in the DL extended with role conjunctions. An alternative technique is the so-called knots technique (Ortiz, Simkus, and Eiter 2008), which is an instance of the mosaic technique originating in Modal Logic. This technique also gives worst-case optimal algorithms for S$\Pi$IQ and several of its sub-logics. Further, there are automata-based decision procedures for positive existential path queries (Calvanese, Eiter, and Ortiz 2007; 2007). Positive existential path queries generalize unions of conjunctive queries and, therefore, decision procedures for this kind of query also provides decision procedures for unions of conjunctive queries. In particular the most recent extension (Calvanese, Eiter, and Ortiz 2007) is very close to a conjunctive query entailment decision procedure for OWL 2, which corresponds to the DL SROIQ, because it covers SRIQ, SROQ, and SROI. The use of the three problematic constructors for nominals, inverses, and number restrictions is, however, not covered.

Regarding data complexity, i.e., the complexity with respect to the ABox (the data) only, CQ entailment is usually NP-complete for expressive logics. For example, for DLs from A$\Sigma$E up to S$\Pi$IQ this is the case (Glimm et al. 2008) and this holds also for CQ entailment in the two variable guarded fragment with counting (Pratt-Hartmann 2009). The latter work is quite closely related since many Description Logics can be translated into the two variable guarded fragment with counting, i.e., the results of Prätt-Hartmann also holds for S$\Pi$IQ with only simple roles (roles that are not transitive and have no transitive subrole) in the query.

Query entailment and answering have also been studied in the context of databases with incomplete information (Rosati 2006b; van der Meyden 1998; Grauine 1991). In this setting, DLs can be used as schema languages, but the expressivity of the considered DLs is usually much lower than the expressivity of the DL $ALCHOTIQb$ that we consider here and reasoning in them is usually tractable. For example, the constructors provided by logics of the DL-Lite family (Calvanese et al. 2007) are chosen such that the standard reasoning tasks are in PTIME and query entailment is in LogSpace with respect to data complexity. Thus, TBox reasoning can be done independently of the ABox and the ABox can be stored and accessed using a standard database SQL engine. Another tractable DL is $EL$ (Baader 2003). Conjunctive query entailment in $EL$ is, however, not tractable as the complexity increases to coNP-complete (Rosati 2007b). Moreover, for $EL^+$ (Baader, Brandt, and Lutz 2005), a still tractable extension of $EL$, query entailment is even undecidable (Krötzsch, Rudolph, and Hitzler 2007). This is mainly because in $EL^+$, one can use unrestricted role compositions. This allows for encoding context-free languages, and conjunctive queries can then be used to check the intersection of such languages, which is known to be an undecidable problem. Since the logics used in databases with incomplete information are considerably less expressive than $ALCHOTIQb$, the techniques developed in that area do not transfer to our setting.

Given that query entailment is a (computationally) harder task than, for example, knowledge base satisfiability, it is not very surprising that decidability of the latter task does not necessarily transfer to the problem of CQ entailment. Most of the undecidability results can be transferred from FOL since many DLs can directly be translated into an equivalent FOL theory. For example, it is known that conjunctive query entailment is undecidable in the two variable fragment of First-Order Logic $L_2$ (Rosati 2007a), and Rosati identifies a relatively small set of constructors that cause the undecidability (most notably role negation axioms, i.e., axioms of the form $\forall x, y (\neg R(x, y) \rightarrow P(x, y))$ for $R, P$ binary predicates). Prätt-Hartmann 2009 recently established decidability for CQ entailment in the two variable guarded fragment with counting ($GC_2$). It is worth noting that Prätt-Hartmann assumes that the background theory (that is the knowledge base in our case) is con-
stant free and formulae of the form \( \exists x \varphi(P(x)) \), which can be used to simulate constants/nominals, are not considered guarded. His result covers, therefore, only the DL \( \text{ALCHOIQ} \) and is not applicable to the case, when the input knowledge base (the background theory) contains nominals (individual constants).

Most of the implemented DL reasoners, e.g., KAON2,\(^1\) Pellet, and RacerPro,\(^2\) provide an interface for conjunctive query answering, although KAON2 and RacerPro consider only named individuals in the ABox for the assignments of variables. Under that restriction queries do no longer have the standard FOL semantics and decidability is obviously not an issue since conjunctive query answering with this restriction can be reduced to standard instance retrieval by replacing the variables with individual names from the ABox and then testing entailment of each conjunct separately. Pellet goes beyond that and also provides an interface for conjunctive queries with FOL semantics under the restriction that the queries have a kind of tree shape. Under this restriction decidability is known since CQs can then be expressed as normal concepts (possibly by adding role conjunctions).

The Big Picture

Before going into the technical details, we will describe our overall line of argumentation establishing decidability of conjunctive query entailment in \( \text{ALCHOIQ} \).

Decidability via Finitely Representable Countermodels. Let \( \mathcal{K} \) be an \( \text{ALCHOIQ} \) knowledge base and \( q \) be the conjunctive query in question, i.e., we aim to determine whether

\[
\mathcal{K} \models q.
\]

Clearly, as \( \text{ALCHOIQ} \) is a fragment of first-order logic with equality, \( \mathcal{K} \) can be translated into a FOL sentence \( \text{FOL}(\mathcal{K}) \). Likewise we find a FOL sentence \( \text{FOL}(q) \) for \( q \) being just an existentially quantified formula. Hence, checking the above entailment is equivalent to determining whether the first-order theory \( \text{FOL}(\mathcal{K}) \) entails \( \text{FOL}(q) \). As a result of the completeness theorem for FOL (Gödel 1929), the consequences of a finite FOL theory are recursively enumerable, which provides us with a procedure that terminates if \( \mathcal{K} \models q \).

Hence, we can establish decidability by providing another algorithm that terminates iff the entailment above does not hold – i.e., if there is a so-called countermodel being a model of \( \mathcal{K} \) for which \( \mathcal{I} \not\models q \).

We will provide such an algorithm by showing that, whenever such a countermodel \( \mathcal{I} \) exists at all, there is also a countermodel \( \mathcal{I} \) that is finitely representable. More precisely, \( \mathcal{I} \) can be encoded into a word \( \text{Rep}(\mathcal{I}) \) of finite length over a finite alphabet, whereby the encoding \( \text{Rep} \) has the property that for every such finite word it can be effectively checked whether it represents a countermodel for a given knowledge base and query.

As a consequence thereof, we can create the desired algorithm that enumerates all words, checks each for being a countermodel, and terminates as soon as it has found one.

Finite Representability by Bounding Nominals and Blocking. We now outline how we are going to show that there is always a finitely representable countermodel, if there is one at all. We do this by taking an arbitrary countermodel and cautiously transforming it into a countermodel that is finitely representable. Cautiously means that we have to make sure that the transformation does preserve the two properties of 1) being a model of the underlying knowledge base \( \mathcal{K} \) and 2) not entailing the considered query \( q \).

The result of the overall transformation is going to be a regular model, i.e., a structure where substructures are being in a certain sense periodically repeated. It is common practice in DL theory to construct this kind of models from arbitrary ones by blocking techniques, whereby certain element configurations occurring twice in the original model are detected and the new model is generated by infinitely stringing together the same finite substructure that is delimited by those two configurations.

In the case we consider, this technique cannot be applied directly to the original countermodel. This is due to an intricate interplay of nominals, inverse roles and cardinality constraints by which an arbitrary – even an infinite – number of domain elements can be forced to “behave” like nominals; this is why those elements are usually referred to as new nominals in a DL setting. In FOL, nominals are often called kings and the new nominals are called the court. In our case, the presence of infinitely many new nominals in the model may prevent the existence of repeated configurations needed for blocking.

We overcome this difficulty by first applying a transformation by means of which the original countermodel is converted into a countermodel with only finitely many new nominals. This guarantees that the subsequent blocking-based transformation is applicable and will yield the desired regular (and thus finitely representable) model.

Bounding Nominals by Transformations of Forest Quasi-Models. For our argumentation, we introduce the notion of forest quasi-models. These are structures not satisfying the originally considered knowledge base but a weakened form of it. In return to this concession, they exhibit a proper forest structure that is easier to handle and manipulate.

We employ two techniques to turn “proper” models into forest quasi-models and vice versa: a model can be unraveled yielding a forest quasi-model. A forest quasi-model can be collapsed to obtain a “proper” model. Both techniques preserve certain structural properties.

Our strategy to construct a countermodel with finitely many nominals consists of the following three steps:

\(^1\)http://kaon2.semanticweb.org
\(^2\)http://www.racer-systems.com
• Take an arbitrary countermodel and unravel it.
• Transform the obtained forest quasi-model by substituting critical parts by well-behaved ones,
• Collapse the obtained structure into a (proper) model.

The mentioned “critical parts” are those giving rise to new nominals. They have to be – at least largely – avoided (we do not care about a finite set of those critical parts remaining).

The central question is: where do these mysterious well-behaved substitutes come from? Fortunately, the plethora of critical parts brings about its own remedy. We thereby obtain parts which have not been present in our structure before, but are well compatible with it and can hence be used for its reorganization.

After having informally introduced our main line of argumentation, we now move on to the technical details.

**Preliminaries**

The basic elements in a DL are atomic concepts (unary predicates), atomic roles (binary predicates), and individuals (constants). In the basic DL $\text{ALC}$, complex concepts can be built from basic ones by using negation ($\neg$), conjunction ($\land$), disjunction ($\lor$), or by quantification over a role ($\forall \, C$), which have typical set-theoretic first-order logic interpretations. The DL $\text{ALCOIF}$ further allows for nominals, which are concepts defined as a singleton set containing a constant ($\{o\}$), inverse roles ($r^{-}$) interpreted as ${\{\langle y, x \rangle \mid \langle x, y \rangle \in r^{-}\}}$, functionality constraints ($\text{func}(f)$), which require that the interpretation of $f$ is a functional relation, and safe Boolean combinations of roles. A Boolean role expression is “safe” if its disjunctive normal form contains a positive conjunct in every disjunct. The DL $\text{ALCOIF}$ further allows for role hierarchies and qualified number restrictions (counting quantifiers), but these features can be eliminated by a polynomial reduction, while preserving query (non-)entailment (Rudolph, Krötzsch, and Hitzler 2008) and, w.l.o.g., we consider only $\text{ALCOIF}$.

In the remainder, we use $A$ and $B$ for atomic concepts, $o$ for an individual name, $r$ for an atomic role, $U$ for a safe Boolean role expression, and $f$ for a role (atomic or inverse) that is declared functional.

An $\text{ALCOIF}$ knowledge base is a finite set of general concept inclusions (GCIs) $C \subseteq D$ ($C \equiv D$ abbreviates $C \subseteq D$ and $D \subseteq C$) and functionality constraints, where $C$ and $D$ are $\text{ALCOIF}$ concepts. W.l.o.g., we do not consider ABoxes since with nominals, the ABox can be internalized into the TBox, and we assume that GCIs are simplified into the following forms:

\[ \bigwedge_{i=0}^{n} A_i \sqsubseteq \bigvee_{j=0}^{m} B_j \quad | \quad A \equiv \{o\} \quad | \quad A \sqsubseteq \forall U.B \quad | \quad A \sqsubseteq \exists U.B \]

If $i = 0$, we interpret $\bigwedge_{i=0}^{n} A_i$ as $\top$ and if $j = 0$, we interpret $\bigvee_{j=0}^{m} B_j$ as $\bot$. We use $\text{con}(\mathcal{K})$, $\text{rol}(\mathcal{K})$, and $\text{nom}(\mathcal{K})$ to denote, respectively, the set of concept, role, and individual names occurring in $\mathcal{K}$, and $\text{cl}(\mathcal{K})$ to denote the closure of $\mathcal{K}$. A role $f$ is (inverse) functional in $\mathcal{K}$ if $\mathcal{K}$ contains an axiom $\text{func}(f)$ (or $\text{func}(f^{-})$).

Let $\mathcal{N}_q$ be a countably infinite set of variables containing $x$ and $y$. An atom is an expression $A(x)$ or $r(x,y)$. A Boolean conjunctive query $q$ is a non-empty set of atoms. We use $\text{var}(q)$ to denote the set of (existentially quantified) variables occurring in $q$ and $\sharp(q)$ for the number of atoms in $q$. For $\mathcal{I} = \langle \Delta^2, \pi \rangle$ an interpretation, $A(x), r(x,y)$ atoms, and $\pi: \text{var}(q) \rightarrow \Delta^2$ a total function, we write (i) $\mathcal{I} \models^= A(x)$ if $\pi(x) \in A^\mathcal{I}$ and (ii) $\mathcal{I} \models^= r(x,y)$ if $\pi(x), \pi(y) \in r^\mathcal{I}$. If $\mathcal{I} \models^= A$ for all atoms $A \in q$, we write $\mathcal{I} \models^= q$ and say that $\mathcal{I}$ satisfies $q$. We write $\mathcal{I} \models q$ if there exists a function $\pi$ such that $\mathcal{I} \models^= q$ and call $\pi$ a match for $q$ in $\mathcal{I}$. If $\mathcal{I} \models K$ implies $\mathcal{I} \models q$, we say that $K$ entails $q$ and write $K \models q$. W.l.o.g., we assume that queries are connected. Given a KB $K$ and a CQ $q$, the query entailment problem is to decide whether $K \models q$.

Unless stated otherwise, we use $q$ for a connected Boolean conjunctive query, $K$ for a simplified $\text{ALCOIF}$ knowledge base, and $\mathcal{I}$ for an interpretation $\langle \Delta^2, \pi \rangle$. As a running example, we use a KB $K$ containing the axioms $\{o\} \sqsubseteq \exists r.A, A \sqsubseteq \exists s.B, B \sqsubseteq C \sqsubseteq D, C \equiv \exists f.E, D \equiv \exists g.E, E \sqsubseteq B \sqcup \{o\}, \text{func}(f^{-}), \text{func}(g^{-})$. Figure 2 a) (p. 6) displays a representation of a model for $K$.

**Model Construction**

We first introduce interpretations and models that have a kind of forest shape. However, the notion of a forest is very weak since we do also allow for arbitrary relations between tree elements and roots.

**Definition 1.** A tree $T$ is a non-empty, prefix-closed subset of $\mathbb{N}^\ast$. A forest $F$ is a subset of $R \times \mathbb{N}^\ast$, where $R$ is a countable, possibly infinite set of elements $\{r_1, \ldots, r_n\}$ such that, for each $r \in R$, the set $\{w \mid (r, w) \in F\}$ is a tree. Each pair $(r, \varepsilon)$ is called a root of $F$. For $(r, w), (r', w') \in F$, we call $(r, w')$ a successor (predecessor) of $(r, w)$ if $r' = r$ and $w' = w \cdot c$ for some $c \in \mathbb{N}$, where $\cdot$ denotes concatenation; $(r', w')$ is a neighbor of $(r, w)$ if $(r', w'')$ is a successor of $(r, w)$ or vice versa. A node $(r, w)$ is an ancestor (descendant) of a node $(r', w')$ if $r' = r$ and $w$ is a prefix of $w'$ ($w'$ is a prefix of $w$). We use $|w|$ to denote the length of $w$. The branching degree $d(w)$ of a node $w$ in a tree $T$ is the number of successors of $w$.

A forest interpretation of $K$ is an interpretation $\mathcal{I}$ that satisfies:

**F1** $\Delta^2$ is a forest with roots $R$;

**F2** there is a total and surjective function $\lambda: \text{nom}(\mathcal{K}) \rightarrow R \times \{\varepsilon\}$ s.t. $\lambda(o) = (r, \varepsilon)$ if $\sigma^2 = (r, \varepsilon)$;

**F3** for each role $r \in \text{rol}(\mathcal{K})$, if $\langle(r, w), (r', w')\rangle \in \Delta^2$, then either $\langle a \rangle w = \varepsilon$ or $w' = \varepsilon$, or $\langle b \rangle (r, w)$ is a neighbor of $(r', w')$. 
If $I \models K$ we say that $I$ is a forest model for $K$. With $\text{nom}(K)$, we denote a knowledge base obtained from $K$ by replacing each nominal concept $\{o\}$ with $o \in \text{nom}(K)$ with a fresh concept name $N_o$. A forest quasi-interpretation for $K$ is an interpretation $\mathcal{J}$ that satisfies $\text{FI1}$ and $\text{FI3}$, and the adapted version $\text{FI2}'$ of $\text{FI2}$ that there is a total and surjective function $\lambda: \text{nom}(K) \rightarrow R \times \{\varepsilon\}$ s.t. $\lambda(o) = (\rho, \varepsilon) \iff (\rho, \varepsilon) \in N_\mathcal{J}$ (there might be other $(\rho, w) \in \Delta^\mathcal{J}$ with $w \neq o$ s.t. $(\rho, w) \in N_\mathcal{J}$). If $I \models \text{nom}(K)$ we say that $I$ is a forest quasi-model for $K$. A forest (quasi) interpretation $I$ is a strict forest (quasi) interpretation if, in condition $\text{FI3}$, only $o$ is allowed; it is a tree interpretation, if it has a single root. If there is a $\delta$ such that $d(w) \leq k$ for each $(\rho, w) \in \Delta^\mathcal{J}$, then we say that $I$ has branching degree $k$.

Let $I, I'$ be two forest interpretations of $K$ with $\delta_1, \delta_2 \in I, \delta_1', \delta_2' \in I'$. The pairs $(\delta_1, \delta_2), (\delta_1', \delta_2')$ are isomorphic w.r.t. $K$, written $(\delta_1, \delta_2) \equiv_K (\delta_1', \delta_2')$ iff

- $(\delta_1, \delta_2) \in r^I \iff (\delta_1', \delta_2') \in r^{I'}$ for each $r \in \text{ro}(K)$,
- $\delta_1 \in A^I \iff (\delta_1', \delta_2') \in A^{I'}$ for each $i \in \{1, 2\}, A \in \text{con}(K)$,
- $\delta = (\delta_1, \delta_2') \in A^I \iff (\delta_1', \delta_2) \in A^{I'}$ for each $i \in \{1, 2\}, o \in \text{nom}(K)$.

We say that $I$ and $I'$ are isomorphic w.r.t. $K$, written: $I \equiv_K I'$, if there is a bijection $\varphi: \Delta^I \rightarrow \Delta^{I'}$ such that, for each $\delta_1, \delta_2 \in \Delta^I$, $(\delta_1, \delta_2) \equiv_K (\varphi(\delta_1), \varphi(\delta_2))$ and $\delta_1$ is a successor of $\delta_2$ iff $\varphi(\delta_1)$ is a successor of $\varphi(\delta_2)$.

If clear from the context, we omit the subscript $K$ of $\equiv_K$ and we extend the definition to forest quasi-interpretations in the obvious way. Forest quasi-models represent, intuitively, an intermediate step between arbitrary models of $K$ and forest models of $K$.

Since KBs are assumed to be simplified, it can mostly be checked locally (by looking at an element of the domain and its direct neighbors) whether an interpretation $I$ is a model of $K$. Only nominals impose a global restriction on the cardinality of concepts. We call an element $\delta \in \Delta^K$ locally $K$-consistent if it satisfies each GCI in $K$ (a functionality restriction $\text{func}(f)$ is satisfied if $\delta$ has at most one $f$-neighbor); $I$ is a model of $K$ if each $\delta \in \Delta^I$ is locally $K$-consistent and, for each $o \in \text{nom}(K)$, there is exactly one element $\delta \in \Delta^I$ such that $\sigma^\mathcal{J} = \delta$. We now show how we can obtain a forest quasi-model from a model of $K$ by using an adapted version of unraveling (Glimm et al. 2008).

**Definition 2.** Let $I$ be a model for $K$ and choose a function that returns, for a concept $C = \exists U.B \in \text{cl}(K)$ and $\delta \in C^I$ some $\delta_C, \delta < \Delta^I$ s.t. $\delta_C \in U^I$ and $\delta_C, \in B^I$. For each $\delta \in C^I \cap C^I$ with $C_1 = \exists U.B_1 \in \text{cl}(K)$ and choose($C_1, \delta$) = $\delta_1$, $i \in \{1, 2\}$, w.l.o.g., we assume that if $(\delta, \delta_1) \equiv (\delta, \delta_2)$, then $\delta_1 = \delta_2$.

An unraveling for some $\delta \in \Delta^I$, denoted $|I, \delta|$, is an interpretation obtained from $I$ and $\delta$ as follows: we define the set $S \subseteq (\Delta^I)^*$ of sequences to be the smallest set such that $\delta$ is a sequence and $\delta_1 \cdots \delta_n \cdot \delta_{n+1}$ is a sequence, if

- $\delta_1 \cdots \delta_n$ is a sequence,
element in a model. In order to identify such elements, we define backwards counting paths as follows:

**Definition 4.** Let \( \mathcal{I} \) be a (quasi) forest model for \( \mathcal{K} \). We call \( p = \delta_1 \cdots \delta_n \) a path from \( \delta_1 \) to \( \delta_n \) if, for each \( i \) with \( 1 \leq i < n \), \( (\delta_i, \delta_{i+1}) \in r_i^e \) for some role \( r_i \in \text{rol}(\mathcal{K}) \). The length \( |p| \) of a path \( p \) is \( n - 1 \). We write \( \delta_1 U_{\delta} \cdots U_{\delta_{n-1}} \delta_n \) to denote that \( (\delta_i, \delta_{i+1}) \in U_I^e \) for each \( 1 \leq i < n \). The path \( p \) is a descending path if there is some \( (\rho, \varepsilon) \in \Delta_I^e \) s.t., for each \( 1 \leq i \leq n, \delta_i = (\rho, w_i) \) and, for each \( 1 \leq i < n, w_i < w_{i+1} \); \( p \) is a backwards counting path (BCP) in \( \mathcal{I} \) if \( \delta_n \in \Delta_{\rho, \varepsilon}^e (\delta_n \in N_{\rho, \varepsilon}^e) \) for some \( \rho \in \text{nom}(\mathcal{K}) \) and, for each \( 1 \leq i < n, (\delta_i, \delta_{i+1}) \in \Delta_{\rho, \varepsilon}^e \) for some inverse functional role \( f_i \); \( p \) is a descending BCP if it is descending and a BCP.

Given a BCP \( p = \delta_1 \cdots \delta_n \) with focus \( \delta_{n+1} \in \Delta_{\rho, \varepsilon}^e \), we call the sequence \( f_1 \cdots f_n \) a path sketch of \( p \).

Let \( \prec \) be a strict total order over \( N_1 \), \( \mathcal{K} \) a consistent ACCOFLb KB, and \( \mathcal{J} \) a forest quasi-interpretation for \( \mathcal{K} \). We extend the order to elements in \( \Delta_{\rho, \varepsilon}^e \) as follows: let \( w_1 = w_p \cdot c_1 \cdots c_i, w_2 = w_p \cdot c_1 \cdots c_i \) where \( w_p \in \mathcal{N}^e \) is the longest common prefix of \( w_1 \) and \( w_2 \), then \( w_1 \prec w_2 \) if either \( n < m \) or both \( n = m \) and \( c_i < c_j \). For \( i \in \{1,2\} \) and \( (\rho, \varepsilon) \in \Delta_{\rho, \varepsilon}^e \), let \( \text{dom}(\mathcal{K}) \) be the smallest nominal such that \( (\rho_i, \varepsilon_i) \in N_{\rho, \varepsilon}^e \). Now \( (\rho_1, w_1) < (\rho_2, w_2) \) if either \( (i) |w_1| < |w_2| \) or \( (ii) |w_1| = |w_2| \) and \( o_1 < o_2 \) or \( (iii) |w_1| = |w_2|, o_1 = o_2 \) and \( w_1 \prec w_2 \). When collapsing, we create new elements of the form \( (\rho, w, \varepsilon) \). We extend, therefore, the order as follows: \( (\rho_1, w_1, \varepsilon_1) < (\rho_2, w_2, \varepsilon_2) \) if \( (\rho_1, w_1, \varepsilon_1) < (\rho_2, w_2, \varepsilon_2) \).

Please note that \( (\rho, w) \) is already a descending BCP if \( (\rho, w) \in \Delta_{\rho, \varepsilon}^e (N_{\rho, \varepsilon}^e) \). We now show how we can “collapse” a forest quasi-model into a forest model provided it satisfies some admissibility restrictions. During the traversal, we distinguish two situations: (i) we encounter an element \( (\rho, w) \) that starts a descending BCP and we have not seen another element before that starts a descending BCP with the same path sketch. In this case, we promote \( (\rho, w) \) to become a new root node of the form \( (\rho, w, \varepsilon) \) and we shift the subtree rooted in \( (\rho, w) \) with it; (ii) we encounter a node \( (\rho, w) \) that starts a descending BCP, but we have already seen a node \( (\rho', w') \) that starts a descending BCP with that path sketch and which is now a root of the form \( (\rho', w', \varepsilon) \). In this case, we delete the subtree rooted in \( (\rho, w) \) and identify \( (\rho, w) \) with \( (\rho', w', \varepsilon) \). If \( (\rho, w) \) is an \( f \)-successor of its predecessor for some inverse functional role \( f \), we delete all \( f \)-successors of \( (\rho', w', \varepsilon) \) and their subtrees in order to satisfy the functionality restriction. We use a notion of collapsing admissibility to characterize models s.t. the predecessor of \( (\rho, w) \) satisfies the same atomic concepts as the deleted successor of \( (\rho', w') \), which ensures that local consistency is preserved.

**Definition 5.** Let \( \mathcal{K}' = \text{nomFree}(\mathcal{K}) \) and \( \mathcal{J} \) a forest quasi-interpretation for \( \mathcal{K} \). We define \( \sim \) as the smallest equivalence relation on \( \Delta_{\rho, \varepsilon}^e \) that satisfies \( \delta_1 \sim \delta_2 \) if \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.

If \( \mathcal{J} \) is a strict forest quasi-model for \( \mathcal{K} \), we call \( \mathcal{J}_0 = \mathcal{J} \) an initial collapsing for \( \mathcal{J} \) and the smallest element \( (\rho_0, w_0) \in \Delta_{\rho, \varepsilon}^e \) such that \( \delta_1, \delta_2 \) start descending BCPs with identical path sketches.
for $J$. The interpretation obtained from $J_w$ by interpreting each $o \in \text{nom}(K)$ as $(p, e) \in N_o^J$ is denoted by collapse($J$) and called a purified interpretation w.r.t. $J$. If collapse($J$) $\models K$, we call collapse($J$) a purified model of $K$.

We use the notion of collapsing-admissibility to characterize quasi-interpretations that become forest models of the KB after we collapse them.

Definition 6. Let $J$ be a forest quasi-interpretation for $K$, then $J$ is collapsing-admissible if there exists a function $ch \colon (cl(K) \times \Delta^J) \to \Delta^J$ s.t., for each $C = \exists U.B \in cl(K)$ and $\delta \in \Delta^J$,

1. $\langle \delta, ch(C, \delta) \rangle \in U^J$, $ch(C, \delta) \in B^J$ and, if there is no functional role $f$ s.t. $\langle \delta, ch(C, \delta) \rangle \in f^J$, then $ch(C, \delta)$ is a successor of $\delta$,

2. if there is some $\delta' \in C^J$ s.t. $\delta$ and $\delta'$ start descending BCPs with identical path sketches, then $\langle \delta, ch(C, \delta) \rangle \equiv \langle \delta', ch(C, \delta') \rangle$.

Since, in unravelings, elements that start (descending) BCPs with identical path sketches have been generated from the same element in the unravelled model, collapsing-admissibility is immediate and the function $ch$ can be defined using the function choose from the unraveling. We can use collapsing-admissibility to show that, whenever we delete an element and the subtree raveling. We can use collapsing-admissibility to show that, whenever we delete an element and the subtree rooted in it during the collapsing, the predecessor of the focus is a suitable replacement.

Lemma 7. Let $J$ be a strict forest quasi-model for $K$ with branching degree $b$ that is collapsing-admissible. Then collapse($J$) is a forest model for $K$ that still has branching degree $b$.

Since unravelings are strict forest quasi-models with bounded branching degree by Lemma 3 and collapsing-admissibility, it is an immediate consequence of Lemma 7 that collapsing an unraveling yields a forest model with bounded branching degree. At this point, the number of roots might still be infinite and we could have obtained the same result by unraveling an arbitrary model, where we take all elements on BCPs as roots instead of taking just the nominals and creating new roots in the collapsing process. In the next sections, however, we show how we can transform an unraveling of a counter-model for the query such that it remains collapsing-admissible and such that it can in the end be collapsed into a forest model with a finite number of roots that is still a counter model for the query. For this transformation it is much more convenient to work with real (strict) trees and forests, which is why use (strict) forest quasi-interpretations.

**Quasi-Entailment in Quasi-Models**

In this section, we provide a characterization for query entailment in forest quasi-models that mirrors query entailment for the corresponding “proper models”. In our further argumentation, we talk about the initial part of a tree, i.e., the part that remains if one cuts branches down to a fixed length. For a forest interpretation $I$ and some $n \in \mathbb{N}$, we denote, therefore, with $\text{cut}_n(I)$ the interpretation obtained from $I$ by restricting $\Delta^J$ to those pairs $(p, w)$ for which $|w| \leq n$. One can show that, in the case of purified models, we find only finitely many unraveling trees of depth $n$ that “look different” (i.e., that are non-isomorphic).

Lemma 8. If $K$ is consistent, then there is a purified interpretation $I$ such that $I \models K$ and, for every $n \in \mathbb{N}$, there are only finitely many non-isomorphic trees of depth $n$.

For our further considerations, we introduce the notion of “anchored $n$-components”. These are certain substructures of forest quasi-interpretations that we use to define a notion of quasi entailment.

Definition 9. Let $J$ be a forest quasi-interpretation and $\delta \in \Delta^J$. An interpretation $C$ is called anchored $n$-component of $J$ with witness $\delta$ if $C$ can be created by restricting $J$ to a set $W \subseteq \Delta^J$ obtained as follows:

- Let $J_\delta$ be the subtree of $J$ that is started by $\delta$ and let $J_{\delta,n} := \text{cut}_n(J_\delta)$. Select a subset $W' \subseteq \Delta^J_{\delta,n}$ that is closed under predecessors.
- For every $\delta' \in W'$, let $P$ be a finite set (possibly empty) of descending BCPs $p$ starting from $\delta'$ and let $W_{\delta'}$ contain all nodes from all $p \in P$.
- Set $W = W' \cup \bigcup_{\delta' \in W'} W_{\delta'}$.

The following definition and lemma employ the notion of anchored $n$-components to come up with the notion of quentailement (short for quasi-entailment), a criterion that reflects query-entailment in the world of forest quasi-models.

Definition 10. Let $J$ be a forest quasi-model for $K$ and $q$ a CQ with $\sharp(q) = n$ and $V = \text{var}(q)$. We say that $J$ quentaile $q$, written $J \models_\Delta q$, if $J$ contains anchored $n$-components $C_1, \ldots, C_\ell$ and there are variable assignment functions $\mu_i \colon V \to 2^{\Delta^J}$ such that:

Q1 For every $x \in V$, there is at least one $C_i$, such that $\mu_i(x) \neq \emptyset$

Q2 For all $A(x) \in q$, we have $\mu_i(x) \subseteq A^J$ for some $i$.

Q3 For every $r(x, y) \in q$ there is a $C_i$ such that there are $\delta_1 \in \mu_i(x)$ and $\delta_2 \in \mu_i(y)$ such that $\langle \delta_1, \delta_2 \rangle \in r^J$.

Q4 If, for some $x \in V$, there are anchored $n$-components $C_i$ and $C_j$ with $\delta \in \mu_i(x)$ and $\delta' \in \mu_j(x)$, then there is

- a sequence $C_{n_1}, \ldots, C_{n_k}$ with $n_1 = i$ and $n_k = j$

- a sequence $\delta_{n_1}, \ldots, \delta_{n_k}$ with $\delta_1 = \delta$ and $\delta_k = \delta'$ as well as $\delta_m \in \mu_{n_m}(x)$ for all $1 \leq m < k$,

such that, for every $m$ with $1 \leq m < k$, we have that

- $C_{n_m}$ contains a descending BCP $p_1$ started by $\delta_m$,

- $C_{n_{m+1}}$ contains a descending BCP $p_2$ started by $\delta_{m+1}$,

- $p_1$ and $p_2$ have the same path sketch.
Note that an anchored component may contain none, one or several instantiations of a variable \( x \in V \). Intuitively, the definition ensures that we find matches of query parts which when fitted together by identifying BCP-equal elements yield a complete query match. In Figure 3, we illustrate the correspondence between entailment and quentailment for the query \( q = \{ (A(x_1), D(x_2), s(x_1, x_2), q(x_3, x_2), s(x_4, x_3), r(x_1, x_4) \} \). The dotted lines indicate a match into the “proper model” (left) and the dashed lines a match into the quasi-model (right) for a single anchored \( n \)-component. Note that the function witnessing the quentailment maps \( x_2 \) to a set containing two elements, but these two elements will be merged during the collapsing process because they are on a BCP.

**Lemma 11.** For any model \( \mathcal{I} \) of \( K \), \( \downarrow(\mathcal{I}) \models q \) implies \( \mathcal{I} \models q \) and, for any collapsing-admissible strict forest quasi-model \( \mathcal{J} \) of \( K \), \( \text{collapse}(\mathcal{J}) \models q \) implies \( \mathcal{J} \models q \).

**Limits and Forest Transformations**

One of the major obstacles for a decision procedure for CQ entailment is that for DLs including inverses, nominals, and cardinality restrictions (or alternatively functionality), there are potentially infinitely many new roots. If we want to eliminate new roots such that only finitely many remain, they have to be replaced by “uncritical” elements. We will construct such elements as “environment-limits” – new domain elements which can be approximated with arbitrary precision by already present domain elements – possibly without themselves being present in the domain.

**Definition 12.** Let \( \mathcal{I} \) be a model of \( K \) and let \( \delta \in \Delta^I \). A tree interpretation \( \mathcal{J} \) is said to be generated by \( \delta \), written: \( \mathcal{J} \triangleright \delta \), if it is isomorphic to the restriction of \( \downarrow(I, \delta) \) to elements of \( \{ (\delta, cw) \mid (\delta, cw) \in \Delta^{I, \delta}, c \notin H \} \) for some \( H \subseteq N \). The set of all interpretations \( \mathcal{I} \), written \( \text{cut}_k(\mathcal{I}) \), are infinitely many \( \delta \in \Delta^I \) with \( \text{cut}_k(\mathcal{I}) \cong \text{cut}_k(\mathcal{J}) \) for some \( \mathcal{L} \triangleright \delta \).

As an analogy, consider the fact that any real number can be approximated by a sequence of rational numbers, even if it is itself irrational.

Figure 4 a) displays a limit element for our example model. The following lemma gives some useful properties of limits.

**Lemma 13.** Let \( K' = \text{nomFree}(K) \), \( \mathcal{I} \) a purified model of \( K \), and \( n \) some fixed natural number. Then the following hold:

1. Let \( L' \) be a tree interpretation such that there are infinitely many \( \delta \in \Delta^I \) with \( L' \cong \text{cut}_n(L) \) for some \( L \triangleright \delta \). Then, there is at least one limit \( \mathcal{J} \in \text{limI} \) such that \( \text{cut}_n(\mathcal{J}) \cong L' \).
2. Every \( \mathcal{J} \in \text{limI} \) is locally \( K' \)-consistent apart from its root \((\rho, \varepsilon)\).
3. For every \( \mathcal{J} \in \text{limI} \), every root \((\rho, \varepsilon)\) in \( \mathcal{J} \) has no BCP to any \((\rho, w) \in \Delta^J \).
4. Every \( \mathcal{J} \in \text{limI} \) is collapsing-admissible.

Having defined and justified limit elements as convenient building blocks for restructuring forest quasi-interpretations, the following definition states how this restructuring is carried out.

**Definition 14.** Let \( \mathcal{I} \) be a model for \( K \) and \( \mathcal{J} \) some forest quasi-model for \( K \) with \( \delta \in \Delta^J \). A strict tree quasi-interpretation \( \mathcal{J}' \in \text{limI} \) is called an \( n \)-secure replacement for \( \delta \) if (i) \( \text{cut}_n((\mathcal{I}, \delta)) \) is isomorphic to \( \text{cut}_n(\mathcal{J}') \) and (ii) for every anchored \( n \)-component of \( \mathcal{J}' \) with witness \( \delta' \), there is an isomorphic anchored \( n \)-component of \( \mathcal{J} \) with witness \( \delta \). If \( \delta \in \Delta^J \) has an \( n \)-secure replacement in \( \text{limI} \), \( \delta \) is \( n \)-replaceable w.r.t. \( \mathcal{I} \) and it is \( n \)-irreplaceable w.r.t. \( \mathcal{I} \) otherwise.

Now, let \( (\rho, w) \in \Delta^J \) be \( n \)-replaceable w.r.t. \( \mathcal{I} \) and \( \mathcal{J}' \) an according \( n \)-replacement for \( (\rho, w) \) from \( \text{limI} \) with root \((\varsigma, \varepsilon)\). The result of replacing \((\rho, w)\) by \( \mathcal{J}' \) is an interpretation \( \mathcal{R} \) with \( \Delta^R = \Delta^J \cup \{(\rho, ww') \mid (\varsigma, w') \in \Delta^J' \} \) for \( \Delta^J_{\text{red}} = \Delta^J \setminus \{(\rho, ww') \mid |w'| > 1\} \) s.t.

- for each \( A \in \text{con}(K') \), \( A^R = (A^J \cap \Delta^J_{\text{red}}) \cup \{(\rho, ww') \mid (\varsigma, w') \in A^J \} \)
- for each \( r \in \text{rol}(K') \), \( r^R = (r^J \cap \Delta^J_{\text{red}} \times \Delta^J_{\text{red}}) \cup \{(\rho, ww'), (\rho, ww'') \mid (\varsigma, w'), (\varsigma, w'') \in r^J \} \)

For \( \mathcal{J} = \downarrow(I) \), an interpretation \( \mathcal{J}' \) is called an \( n \)-secure transformation of \( \mathcal{J} \) if it is obtained by (possibly infinitely) repeating the following step:

Choose one unvisited w.r.t. tree-depth minimal node \((\rho, w)\) that is \( n \)-replaceable w.r.t. \( \mathcal{I} \). Replace \((\rho, w)\) with one of its \( n \)-secure replacements from \( \text{limI} \) and mark \((\rho, w)\) as visited.

Figure 4 a) displays a 2-secure replacement in the considered unraveling of our example model shown in Figure 4 b). Figure 4 c) displays the result of carrying out this replacement step on our example. The following lemma ensures that not too many elements (actually defined in terms of the original model) are exempt from being replaced.

**Lemma 15.** Every purified model \( \mathcal{I} \) of \( K \) contains only finitely many distinct elements that start a BCP and are the cause for \( n \)-irreplaceable nodes in the unraveling of \( \mathcal{I} \).
Proof. Assume the converse: let a purified model \( \mathcal{I} \) of \( \mathcal{K} \) contain an infinite set \( D \) of elements giving rise to \( n \)-irreplaceable nodes in \( \downarrow(\mathcal{I}) \). Then there must be an \( \mathcal{L} \) such that there is an infinite set \( D' \subseteq D \) such that every \( d' \in D' \) generates an \( \mathcal{L} \) for which \( \text{cut}_n(\mathcal{L}) \cong \mathcal{L} \) (since by Lemma 8, there are only finitely many non-isomorphic choices for \( \mathcal{L} \)). This set \( D' \) can be used to guide the construction of a specific limit element \( J \in \lim \mathcal{I} \) according to Lemma 13.1. Now, for an element \((p, w)\) from \( J \) starting a BCP, let \( l_{(p, w)} \in \mathbb{N} \) be the length of the shortest such BCP starting from \((p, w)\). Then, let \( k \) be the maximum over all \( l_{(p, w)} \) of individuals \((p, w)\) from \( J \) that start a BCP and for which \(|w| \leq n\). By construction, \( D' \) contains one element \( d'' \) generating an \( \mathcal{L} \) with \( \text{cut}_k(\mathcal{L}) \cong \text{cut}_k(J) \) (actually infinitely many). By the choice of \( k \), we can conclude that \( J \) is an \( n \)-secure replacement for the irreplaceable \( J \)-node caused by \( d'' \) which gives us a contradiction.

Next, we can show that the process of unraveling, \( n \)-secure transformation and collapsing preserves the property of being a model of a knowledge base and (with the right choice of \( n \)) also preserves the property of not entailing a conjunctive query. Moreover, this model conversion process ensures that the resulting model contains only finitely many new nominals witnessed by a bound on the length of BCPs. Figure 4 d) illustrates these properties for our example model. Note that only one new nominal is left whereas collapsing the original unraveling yields infinitely many.

Lemma 16. Let \( \mathcal{I} \) be a purified model of \( \mathcal{K} \), \( J = \downarrow(\mathcal{I}) \), and \( J' \) an \( n \)-secure transformation of \( J \). Then the following hold:

1. collapse(\( J' \)) is a model of \( \mathcal{K} \).
2. There is a natural number \( m \) such that \( J' \) does not contain any node whose shortest descending BCP has a length greater than \( m \).
3. If, for some CQ \( q \), we have \( \mathcal{I} \not\models q \) and \( n > z(q) \), then \( J' \not\models q \).
4. If, for some CQ \( q \), we have \( \mathcal{I} \not\models q \) and \( n > z(q) \), then collapse(\( J' \)) \( \not\models q \).

Now we are able to establish our first milestone on the way to showing finite representability of countermodels.

Theorem 17. For every ALCOT,Fb KB \( \mathcal{K} \) and CQ \( q \) s.t. \( \mathcal{K} \not\models q \), there is a forest model \( \mathcal{I} \) of \( \mathcal{K} \) with finitely many roots and bounded branching degree s.t. \( \mathcal{I} \not\models q \).

Finite Representations of Models

We can now use standard techniques from tableau algorithms (adapted to work on models) to construct finite representations for a forest model of \( \mathcal{K} \) with finitely many roots. In particular the tableau algorithm with \( n \)-tree-blocking, \( n \geq z(q) \), for deciding CQ entailment in SHIQ, SHIQ1, and SHIQ2 with only simple roles in the query (Ortiz 2008; Ortiz, Calvanese, and Eiter 2008) works exactly like that. We call an interpretation, on which we applied \( n \)-tree-blocking and discarded all blocked elements, an \( n \)-representation. Such an \( n \)-representation corresponds to a complete and clash-free completion graph in tableau algorithms.

Definition 18. Let \( n \in \mathbb{N} \) be a fixed natural number and \( \mathcal{I} \) with \((\delta, w) \in \Delta^\mathcal{I}, w \not\in \varepsilon\) a forest interpretation for \( \mathcal{K} \). An \( n \)-blocking-tree w.r.t. \((\delta, w), \) denoted \( \text{block}_n^\mathcal{K}(\delta, w), \) is the interpretation obtained from \( \mathcal{I} \) by restricting \( \mathcal{I} \) to elements in \( \{ (\delta, w w') \mid |w'| \leq n \} \cup \{ (\rho, \varepsilon) \mid (\rho, \varepsilon) \in \Delta^\mathcal{I} \}. \) An \( n \)-blocking-tree \( \text{block}_n^\mathcal{K}(\delta, w) \text{-blocks} \) \( \text{block}_n^\mathcal{K}(\delta, w w') \) if

1. \( \text{block}_n^\mathcal{K}(\delta, w) \) and \( \text{block}_n^\mathcal{K}(\delta, w w') \) have disjoint domains except for root elements,
2. there is a bijection \( \varphi \) from elements in \( \text{block}_n^\mathcal{K}(\delta, w) \) to elements in \( \text{block}_n^\mathcal{K}(\delta, w w') \) that witnesses \( \text{block}_n^\mathcal{K}(\delta, w) \cong \text{block}_n^\mathcal{K}(\delta, w w'), \) and
3. for each descendant \((\delta, w w')\) of \((\delta, w), \) there is no inverse functional role \( f \) and root \((\rho, \varepsilon) \in \Delta^\mathcal{I} \) such that \( (\delta, w w'), (\rho, \varepsilon) \in f^\mathcal{I}. \)

A node \((\delta, v) \in \Delta^\mathcal{I} \) is \( n \)-blocked, if \((\delta, v) \) is either directly or indirectly \( n \)-blocked; \((\delta, v) \) is \( n \)-blocked, if one of its ancestors is \( n \)-blocked; \((\delta, v) \) is \( n \)-blocked if none of its ancestors is \( n \)-blocked and \((\delta, v) \) is a leaf of some \( n \)-blocking-tree \( \text{block}_n^\mathcal{K}(\delta, w w') \) in \( \mathcal{I} \) that is not blocked. W.l.o.g., we assume that the \( n \)-blocking-trees are minimal w.r.t. the order over \( \Delta^\mathcal{I} \) (cf. Def. 4).

A forest interpretation \( \mathcal{I} = (\Delta^\mathcal{I}, \mathcal{I}) \) for \( \mathcal{K} \) is an \( n \)-representation of \( \mathcal{K} \) if (i) \( \Delta^\mathcal{I} \) is finite, (ii) \( \Delta^\mathcal{I} \) contains...
Lemma 20. Let $\mathcal{K}$ be a consistent $\mathcal{ALCQIQB}$ knowledge base, $q$ a conjunctive query, and $n \geq \sharp(q)$. If $R$ is an $n$-representation of $\mathcal{K}$ such that $R \not\models q$, then there is a model $I$ of $\mathcal{K}$ s.t. $I \not\models q$.

Now Lemma 19 guarantees that, in case $\mathcal{K} \not\models q$, there is always a finite $n$-representation $R$ for $\mathcal{K}$ such that $R \not\models q$ and Lemma 20 guarantees that $R$ can be transformed into a model $I$ of $\mathcal{K}$ such that $I \not\models q$. This suffices to show that we can enumerate all (finite) $n$-representations for $\mathcal{K}$ and check whether they entail the query. Since role hierarchies and qualified number restrictions can be encoded in $\mathcal{ALCQI}$, we get, together with the semi-decidability result for FOL (Gödel 1929), the desired theorem.

Theorem 21. It is decidable whether $\mathcal{K} \models q$ for $\mathcal{K}$ an $\mathcal{ALCQIQB}$ knowledge base and $q$ a Boolean conjunctive query.

Conclusions

This solves the long-standing open problem of deciding conjunctive query entailment in the presence of nominals, inverse roles, and qualified number restrictions. Our result generalizes to unions of conjunctive queries and to $\mathcal{SHOIQ}$ provided the query contains only simple roles, and we are confident that the technique also extends to $\mathcal{SROIQ}$ under the same restriction.

Entailment of unions of conjunctive queries is also closely related to the problem of adding rules to a DL knowledge base, e.g., in the form of Datalog rules. Augmenting a DL KB with an arbitrary Datalog program easily leads to undecidability (Levy and Rousset 1998). To ensure decidability, the interaction between the Datalog rules and the DL knowledge base can be restricted by imposing a safeness condition. The $\mathcal{DL}+$-log framework (Rosati 2006a) provides the least restrictive integration proposed so far and Rosati presents an algorithm that decides the consistency of a $\mathcal{DL}+$-log knowledge base by reducing the problem to entailment of unions of conjunctive queries. Notably, his results (Rosati 2006a, Thm. 11) imply that the consistency of an $\mathcal{ALCQIQB}$ knowledge base extended with (weakly-safe) Datalog rules is decidable if and only if entailment of unions of conjunctive queries in $\mathcal{ALCQIQB}$ is decidable, which we have established.

Corollary 22. The consistency of $\mathcal{ALCQIQB}+$-log-knowledge bases (both under FOL semantics and under non-monotonic semantics) is decidable.

Another related reasoning problem is query containment. Given a schema (or TBox) $S$ and two queries $q$ and $q'$, we have that $q$ is contained in $q'$ w.r.t. $S$ iff every interpretation $I$ that satisfies $S$ and $q$ also satisfies $q'$. It is well known that query containment w.r.t. a TBox can be reduced to deciding entailment for unions of conjunctive queries w.r.t. a knowledge base (Calvanese, De Giacomo, and Lenzerini 1998). Decidability of unions of conjunctive query entailment in $\mathcal{ALCQIQB}$ implies, therefore, also decidability of query containment w.r.t. to an $\mathcal{ALCQI}$ TBox.

There are two obvious avenues for future work. Firstly, we will embark on extending our results in order to allow non-simple roles as query predicates. This is a non-trivial task as our current approach heavily relies on a certain locality of query matches, which has to be relinquished when considering non-simple roles. Secondly, since the approach is purely a decision procedure, the computational complexity of the problem remains open, and we are eager to determine the associated computational complexities and provide techniques that can form the basis for implementable algorithms.
